Function and system design

Colorimetric measuring principle

After sample preparation, some of the permeate is pumped into the mixing/reaction chamber. The chemical reaction causes the characteristic change in the color of the sample. The photometer determines the level of absorption by the sample at defined wavelengths. The analyzed wavelengths, and their relationships to one another, are parameter-specific.

Based on proportionality, the amount of light absorption is a direct indicator of the concentration of the parameter under analysis in the sample. To compensate for potential interferences, a reference measurement is used in addition to the measured signal. This reference signal is subtracted from the measuring signal. The temperature in the photometer is kept constant to ensure a reproducible reaction that takes place within a short period of time.

1 LED unit (for measurement/reference)
2 Cuvette - mixing and reaction vessel
3 Detector (for measurement/reference)

Total hardness

The total hardness of water is a measure of the concentrations of magnesium and calcium ions that are dissolved in the water.

Photometric determination of total hardness

The addition of MgEDTA causes calcium to be replaced by magnesium in the same ratio. Magnesium reacts with calmagite in the basic range to form a violet dye. The absorption is measured at a wavelength of 635 nm.

The amount of light absorption is proportional to the total hardness in the sample.

Cross-sensitivity

The ions listed were checked with the specified concentrations. A summary effect has not been studied. No cross-sensitivities were observed up to the concentration levels indicated.

0.7 mg/l (ppm)	Fe^{2+}
0.1 mg/l (ppm)	Cu^{2+}
0.1 mg/l (ppm)	Cr^{3+}
4 to 10	pH

Due to the method used, elevated levels of Zn^{2+} and Mn^{2+} may lead to false positive results.
