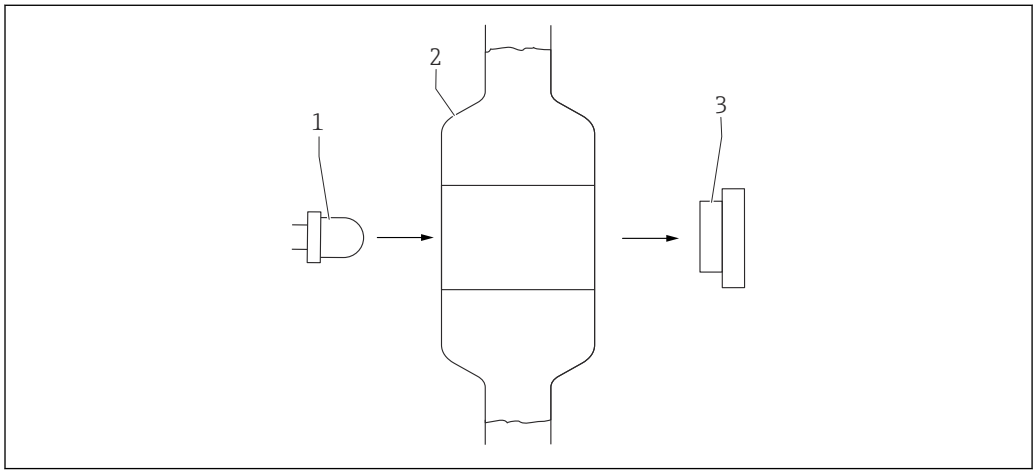
Function and system design

Measuring principle for chemical oxygen demand

As a sum parameter, the chemical oxygen demand, or COD, describes the amount of oxygen that is needed to fully oxidize all the oxidizable substances in a sample.

To determine the chemical oxygen demand, the chloride ions in the sample must first be removed as they would interfere with the measurement result. This is done by adding mercuric sulfate. Once the chloride ions have been removed, the sample is digested at a temperature of 175 °C by adding sulfuric acid, silver sulfate and potassium dichromate. Silver sulfate acts as the catalyst here. The high temperature and potassium dichromate - a very strong oxidizing agent - ensure that the sample is digested quickly and completely. The digestion time required can be additionally shortened by the pressure reactor of the CA80COD.



1 Measuring cell

1 LED unit (for measurement/reference)
2 Photometer cuvette - mixing and reaction vessel
3 Detector (for measurement/reference)

The oxidizing agent itself is reduced from Cr^{6+} to Cr^{3+} during the chemical reaction. This is associated with the color of the solution changing from orange to green. The reduction of the chromate and the color change are directly proportional to the concentration of oxidizable substances in the sample. The optical quantification of the reduced chromate amount can therefore be used as an indicator of the chemical oxygen demand of the sample.

Cross-sensitivity

The ions listed were checked with the specified concentrations. A summary effect has not been studied. No cross-sensitivities were observed up to the concentration levels indicated.

20 000 mg/l (ppm)	$(NH_4)_2SO_4$
5000 mg/l (ppm)	NaCl

Oxidizable substances

The substances oxidized by the COD method are primarily organic carbon compounds. Alongside this some inorganic compounds, such as iodide and nitrite, are also oxidized.

A complete measuring system comprises:
- Analyzer Liquiline System CA80COD with the configuration ordered

Customer-specific solution

Prior to analysis, the sample must be prepared at the customer site so that it is and homogeneous (representative sample). The sample can be supplied to an external collecting vessel . The customer-specific sample preparation system must have its own individual control unit.

The version of the Liquiline System CA80 as a self-priming device does not have a collecting vessel with level detection. For this reason, a continuous supply of sample must be guaranteed on the process side.

Y strainer (optional)

With the Y strainer it is possible to directly take samples containing particles from the pipes. It is therefore also suitable for the COD analysis procedure where particles up to a certain size must also be included in the analysis.
